Chapter 1

Preliminaries

The “preliminaries” that are discussed here will extend to using the R Commander menu to draw graphs!

1.1 Installation of R and of R Packages

**Installation of R**
First download and install R from a CRAN site, e.g.

- [http://cran.ms.unimelb.edu.au/](http://cran.ms.unimelb.edu.au/)

Windows an MacOS X users should download the relevant executable, (e.g. `R-2.7.0-win32.exe` for Windows, or `R-2.7.0.dmg` for MacOS X), and open the downloaded file (e.g., click on it) to start installation.

**Installation of R Packages (Windows & MacOS X)**
Start R (e.g., click on the R icon). Then use the relevant menu item to install packages via an internet connection. This is (usually) easier than downloading, then installing.

**Locating packages**
The CRAN task views may be a good first place to go.

For installation, follow the instructions in the text box. For installing packages, Windows users will first need to specify a mirror. In Australia, specify the Australian mirror.

A fresh install is typically required to take advantage of new major releases (e.g. moving from a 2.6 series release to a 2.7 series release) when they appear. For working through these notes, version 2.7.0 or later should be installed.

1.1.1 Installation of packages from the command line

For packages where there are dependencies, installation from the command line may be an attractive way to go. First, start R, perhaps by clicking on an R icon. Make sure that you have a live internet connection.

For the R Commander, enter:

```
install.packages("Rcmdr", dependencies=TRUE)
```

Doing the installation this way ensures that other packages that R Commander may want get installed at the same time. One of those packages is the `rgl` 3D graphics package that I will describe briefly. Other graphics packages that this installs are `scatterplot3d`, `vcd` (visualization of categorical data) and `colorspace` (for generation of color palettes, etc).
A further package that will be discussed here, the `ggplot2` package, is not an R commander suggested package, and requires separate installation. Enter, at the command line:

```
install("ggplot2", dependencies=TRUE)
```

### 1.2 The R Commander

### 1.3 The R Commander GUI

The R commander gives a graphical user interface (GUI) to a wide range of abilities, in the base R system and in R packages. This includes graphical abilities, in the `lattice` and `rgl` packages as well as in base graphics.

To start the R commander, start up R and enter:

```r
library(Rcmdr)
```

This opens an R Commander script window, with the output window underneath. This window can be closed by clicking on the × in the top left corner. If thus closed, enter `Commander()` to reopen it again later in the session.

**The R Commander GUI – a guide to getting started**

Once the points that will now be noted are understood, use of the R Commander should for the most part be straightforward.

**From GUI to writing code:** The R commander displays the code that it generates. Users can take this code, modify it, and re-run it. The code can be run either from the R Commander script window or from the R console window (if open).

**The active data set:** The R commander has the notion of an active data set. Here are alternative ways to make a data set active. Start by clicking on the Data drop-down menu. Then

- Click on **Active data set**, and pick from among data sets, if any, in the workspace.
- Click on **Import data**, and follow instructions, to read in data from a file. The data set is read into the workspace, at the same time becoming the active data set.
- Click on **New data set . . .**, then entering data via a spreadsheet-like interface.
- Click on **Data in packages**, click on Read Data from Package, then identify one of the attached packages and choose a data set from among those that are included with the package.
- A further possibility is to load data from an R image (.RData) file; click on **Load data set . . .**

**Creating graphs:** To draw graphs, click on the Graphs drop-down menu. Then

- Click on **Scatterplot . . .** to obtain a scatterplot. This uses the function `scatterplot()` from the `car` package, which is an option rich interface to functions that are in base graphics.
- Click on **X Y conditioning plot . . .** for lattice scatterplots and panels of scatterplots.
- Click on **3D graph** to obtain a 3D scatterplot, using the R Commander function `scatter3d()` that is an interface to functions in the `rgl` package.

---

1 At startup, the R Commander checks whether all the suggested packages, needed to use all its features, are available. If some are missing, then upon starting up, the R commander offers to install them. For installing such packages, there must be a live internet connection.
Statistics (& fitting models): Click on the Statistics drop down menu to get submenus that give summary statistics and/or carry out various statistical tests. This includes (under Contingency tables) tables of counts and (under Means) One-way ANOVA. Also, click here to get access to the Fit models submenu.

*Models:* Click here to extract information from model objects once they have been fitted. (NB: To fit a model, go to the Statistics drop down menu, and click on Fit models).
Chapter 2

Base Graphics

Base Graphics implements a relatively “traditional” style of graphics:
Plots go to one or more pages of a graphics device (screen, or hardcopy)

plot(), etc. Sets up figure region, with user region inside, usually starts the graph.
Other functions that initiate a graph include hist() and boxplot().
Typically, it also creates the main part, or all, of the graph.
Use points(), lines(), text(), mtext(), axis(), rug(), identify(), etc., to add to the graph.

Plot y vs x with(women, plot(height, weight)) # Older syntax
plot(weight ~ height, data=women) # Newer syntax (graphics formula)

Caveat Some base graphics functions do not take a data parameter

To see some of the possibilities that traditional (or base) R graphics offers, enter
demo(graphics)

Press the Enter key to move to each new graph.

2.1 plot() and allied functions

Here are two examples.

library(DAAG)
attach(elasticband) # R can now find distance & stretch
plot(distance ~ stretch)
plot(ACT ~ year, data=austpop, type="l")
plot(ACT ~ year, data=austpop, type="b")
detach(elasticband)

Figure 2.1 demonstrates some of the features of base graphics. Base graphics is highly flexible, but often requires a great deal of attention to detail. There are annoying inconsistencies.

2.1.1 Fine control – parameter settings

Users who execute the code given above for Figure 2.1 will notice that the layout is different; there will be bigger margins, and the tick labels and the axis labels will be further out. To get the layout shown, there were some small changes to parameter settings:

## Invoke once device is open, and before starting the plot
oldpar <- par(mar = rep(2,4), xaxs="i", yaxs="i", mgp=c(1.5,0.75,0))
## A: Set up plotting region, but (type="n") do not plot. Suppress axes & axis labels
plot(0 ~ 0, xlim=c(0, 26.5), ylim=c(-0.05, 34.25), xlab='', ylab='', type="n", axes=FALSE)

## B: Plot symbols 0 – 25. Overlay with numbers 0 – 25
grayscale <- gray(seq(from=0.1, by=0.05, length=13))
xpos <- seq(from=1, by=2, length=13);  ypos <- rep(23,13); ypos2 <- ypos-2
points(ypos ~ xpos, cex=3, col=grayscale, pch=0:12)
points(ypos2 ~ xpos, cex=3, col=rev(grayscale), pch=13:25)
text(ypos ~ xpos, labels=paste(0:12), cex=0.75)
text(ypos2 ~ xpos, labels=paste(13:25), cex=0.75)

## C: Enlarged and/or coloured symbols or text
xpos <- c(21.5, 23.5, 25.5);  ypos <- rep(18, 3); ypos2 <- ypos-2
points(ypos ~ xpos, pch=0:2, cex=4:2, col=gray(c(.2, .4, .6)))
text(ypos2 ~ xpos, labels=letters[1:3], cex=2:4, col=gray(c(.2, .4, .6)))

## D: Positioning of label with respect to a point
xpos <- c(22.5, 21.5, 22.5, 23.5)
ypos <- c(10, 11, 12, 11)
points(ypos ~ xpos, pch=16, cex=1.5, col=gray((1:4)/5))
posText <- c("below (pos=1)", "left (2)", "above (3)", "right (4)"

text(ypos ~ xpos, posText, pos=1:4)

## E: Sides (margins) are numbered 1, ...4. Label them acordingly
mtext(side=4, line=0.5, text="Side 4", adj=1) # Flush right on margin (Flush left: adj=0)
## Center labels in margins 1 to 3
for (i in 1:3) mtext(side=i, line=0.5, text=paste("Side",i))
## Label selected plotting positions
labpos <- c(0, 10:12, 16, 18, 21, 23)
for (pos in labpos) axis(side=4, at=pos, las=2)

Figure 2.1: Here are illustrated a number of features of traditional graphics plots. The code reproduces the points, labels, ticks, tick labels and axis labels, but not the printing of the code in the figure region.
The existing parameter settings are stored in oldpar, so that they can be restored later. Margins are reduced in size (mar = rep(2,4)) so that each margin has room for two lines of text only. The figure area will take in the exact x- and y-limits (xaxs=“i”, yaxs=“i”), rather than extending slightly beyond those limits. The margin parameters are set so that labels will be printed 1.5 lines out from the margin, tick labels 0.75 lines out from the margin, and ticks right on the margin.

Here are some of the more common settings:

- Plotting symbols: pch (choice of symbol); cex ("character expansion"); col (color). Thus par(cex=1.2) increases the plot symbol size 20% above the default.

- Lines: lty (line type); lwd (line width); col (color).

- Axis limits: xlim; ylim. (Assuming xaxs="r", x-axis limits are by default extended by 4% relative to the data limits. Specify xaxs="i" to make the default an exact fit to the data limits. For the y-axis, replace xaxs by yaxs and x by y.)

- Axis annotation and labels: cex.axis (character expansion for axis annotation, independently of cex); cex.labels (size of the axis labels); mgp (margin line for the axis title, axis labels, and axis line; default is mgp=c(3, 1, 0)).

- Graph margins: mar (inner margins, clockwise from the bottom; the out of the box default is mar=c(5.1, 4.1, 4.1, 2.1), in lines out from the axis); oma (outer margins, relevant when there are multiple graphs on the one graphics page).

- Plot shape: pty="s" gives a square plot (must be set using par()).

- Multiple graphs on the one graphics page: Specify par(mfrow=c(m,n)) to get an m rows by n columns layout of graphs on a page.

Type help(par) to get a (very extensive) complete list.

In most (not all) instances, the change can be made either in a call to a plotting function (eg, plot(), points()), or using par(). If made in a call to a plotting function, the change applies only to that call. If made using par(), changes remain in place until changed again, or until a new device is opened.

2.1.2 Adding points, lines and text – examples

Here is a simple example (Figure 2.2) that uses the function text() to label the points on a plot.

Code that gives the above plot is:

```
> ## Data used in plot
> primates # DAAG package

<table>
<thead>
<tr>
<th></th>
<th>Bodywt</th>
<th>Brainwt</th>
</tr>
</thead>
<tbody>
<tr>
<td>Potar monkey</td>
<td>10.0</td>
<td>115</td>
</tr>
<tr>
<td>Gorilla</td>
<td>207.0</td>
<td>406</td>
</tr>
<tr>
<td>Human</td>
<td>62.0</td>
<td>1320</td>
</tr>
<tr>
<td>Rhesus monkey</td>
<td>6.8</td>
<td>179</td>
</tr>
<tr>
<td>Chimp</td>
<td>52.2</td>
<td>440</td>
</tr>
</tbody>
</table>
```
2.2 Plotting Mathematical Symbols

Lattice, as well as base graphics users, can take advantage of the features described here.

Both `text()` and `mtext()` will take an expression rather than a text string, as in the x-axis label of Figure 2.3. Observe that an arbitrary character string can appear as a variable in an expression. The operator `*` juxtaposes the separate elements of the “expression”.

Note that `=` must appear as `==`, as in:

```r
par(family="Times")
plot(hg ~ rcc, data=ais,
     xlab=expression("Red cell count ("
                     * 10^12 * italic(l)^{-1}
                     ")") ,
     ylab=expression("Hemaglobin ("
                     * g*dot(""
                     * daL^{-1} * ")" )))
```

2.3 Summary

The functions `plot()`, `points()`, `lines()`, `text()`, `mtext()`, `axis()`, `identify()` etc. form a suite that plots points, lines and text.

Note the alternatives `plot(x, y), plot(y ~ x)`

2.4 Exercises

1. Check the distributions of head lengths (`hdlngth`) in the `possum` data set. Compare the following forms of display:
   a) a histogram (`hist(possum$hd1ngth)`);
   b) a stem and leaf plot (`stem(qqnorm(possum$hd1ngth))`);
   c) a normal probability plot (`qqnorm(possum$hd1ngth)`); and

---

```r
attach(primates)
plot(Bodywt, Brainwt, xlim=c(0, 250),
     xlab="Body weight (kg)", ylab="Brain weight (g)"
     # Specify xlim so that there is room for the labels
     text(x=Bodywt, y=Brainwt, labels=rownames(primates), pos=4)
     # Alternatives are pos=1 (below), 2 (left), 3 (above)
detach(primates)
```
d) a density plot (plot(density(possum$hdlngth)).
What are the advantages and disadvantages of these different forms of display?

2. For the columns of the data frame nihills, examine the distribution using histograms, density plots and normal probability plots.
Repeat the exercise with the logarithms of the data values.

3. Use mfrow() to set up the layout for a 3 by 4 array of plots. In the top 4 rows, show normal probability plots for four separate ‘random’ samples of size 10, all from a normal distribution. In the middle 4 rows, display plots for samples of size 100. In the bottom four rows, display plots for samples of size 1000. Comment on how the appearance of the plots changes as the sample size changes.

4. (a) The function runif() can be used to generate a sample from a uniform distribution, by default on the interval 0 to 1. Try x <- runif(10), and print out the numbers you get. Then repeat exercise 6 above, but taking samples from a uniform distribution rather than from a normal distribution. What shape do the points follow?
(b) Repeat exercise (a), but for other distributions such as chi-square (rchisq()) and t (rt()) (try, e.g., degrees of freedom 1, 5 and 40).

5. The data set LakeHuron (datasets package) has mean July average water surface elevations, in feet, IGLD (1955) for Harbor Beach, Michigan, on Lake Huron, Station 5014, for 1875-1972. Use the following to create a data frame that has the same information:

```r
huron <- data.frame(year=as(time(LakeHuron), "vector"),
                     mean.height=LakeHuron)
```

a) Plot mean.height against year.
b) Use identify() to determine which years correspond to the lowest and highest mean levels. That is, type

```r
identify(huron$year, huron$mean.height, labels=huron$year)
```
and use the left mouse button to click on the lowest point and highest point on the plot. To quit, press both mouse buttons simultaneously.
c) As in the case of many time series, the mean levels are correlated from year to year. To see how each year’s mean level is related to the previous year’s mean level, use

```r
lag.plot(huron$mean.height)
```
This plots the mean level at year $i$ against the mean level at year $i-1$.
d) *Now explain why the following code achieves the same effect:

```r
plot(LakeHuron)
identify(LakeHuron, labels=time(LakeHuron))
```
e) *Use the function acf() to plot the autocorrelation function. Compare with the result from the pacf() (partial autocorrelation). What are the graphs telling you? (For an explanation of the autocorrelation function, look up “Autocorrelation” on Wikipedia.)
Chapter 3

Lattice Graphics

3.1 Lattice Graphics

<table>
<thead>
<tr>
<th>Lattice Graphics:</th>
</tr>
</thead>
<tbody>
<tr>
<td><strong>Lattice</strong></td>
</tr>
<tr>
<td><strong>Grid</strong></td>
</tr>
<tr>
<td><strong>Lattice vs base</strong></td>
</tr>
<tr>
<td><strong>Lattice syntax</strong></td>
</tr>
</tbody>
</table>

Lattice (trellis) graphics functions allow the use of the layout on the page to reflect meaningful aspects of data structure. Different levels of a factor may appear in different panels. Or they may appear in the same panel, distinguished by color and/or symbol. If lines or smooth curves are added, there is a different line or curve for each different group.

Similar considerations apply when columns of data are plotted in parallel. Different columns may appear in different panels. Or they may appear in the same panel, distinguished by color and/or symbol.

The lattice package comes already installed with all the binary distributions that are supplied from CRAN (Comprehensive R Archive Network: [http://mirror.aarnet.edu.au/pub//CRAN/](http://mirror.aarnet.edu.au/pub//CRAN/)).

To see some of the possibilities that lattice graphics offers, enter

```r
library(lattice) # For use, the lattice package must be attached
demo(lattice)
```

The `lattice` package implements a *trellis* style of graphics, as in the S+ implementation of the S language.

**Lattice graphics versus base graphics – xyplot() versus plot()**

A `Brainwt` versus `Bodywt` scatterplot for the `primates` data, such as was given earlier, might alternatively have been obtained using the function the function `xyplot()` from the `lattice` package. The following, when typed on the command line, give a plot on the graphics device:

```r
## Plot Brainwt vs Bodywt, data frame primates (DAAG)
plot(Brainwt ~ Bodywt, data=primates) # base graphics
```
CHAPTER 3. LATTICE GRAPHICS

# 'base' graphics use the abilities of the graphics package
library(lattice)
xyplot(Brainwt ~ Bodywt, data=primates)  # lattice

The mechanism that yields the plot is different in the two cases:

• plot() gives a graph as a side effect of the command.
• xyplot() generates a graphics object. As this is output to the command line, the object is “printed”, i.e., a graph appears.

The following illustrates the difference between the two functions:

invisible(plot(Brainwt ~ Bodywt, data=primates))  # Graph appears
invisible(xyplot(Brainwt ~ Bodywt, data=primates))  # No graph

The function invisible() suppresses command line printing, so that invisible(xyplot(...)) does not yield a graph.

Inside a function, xyplot(...) prints a graph only if it is the return value from the function, i.e. usually, is on the final line. In a file that is sourced (use source(), no graph will appear. Inside a function (except as mentioned), or in a file that is sourced, there must be an explicit print(), i.e.

print(xyplot(ACT ~ year, data=austpop))

Lattice functions create trellis objects. Trellis objects can be created even if no device is open. Such objects can be updated. Objects are plotted (by this time, a device must be open), either when output from a lattice function goes to the command line (thus implicitly invoking the print() command), or by the explicit use of print().

By successively updating a trellis graphics object, it can be built up and/or modified in steps. Additionally, it is possible to add to a “printed” or displayed graphics page. Subsection 3.1.5 will show how to do this.

Panels of scatterplots – the use of xyplot()

Graphics functions in the lattice package, are designed to allow row by column layouts of panels. Different panels are for different subsets of the data. Additionally, points can be distinguished, within panels, according to some further grouping within the data.

The ais dataset (DAAG) has data on elite Australian athletes who trained at the Australian Institute of Sport. Data were collected with a view to studying possible differences in blood characteristics, between athletes in endurance-related events and those in power-related events. The help page for ais has details of the measurements, including a variety of blood cell counts.

Here is a breakdown, by sex and sport, of numbers:

> with(ais, table(sex, sport))

<table>
<thead>
<tr>
<th>sport</th>
<th>B_Ball</th>
<th>Field</th>
<th>Gym</th>
<th>Netball</th>
<th>Row</th>
<th>Swim</th>
<th>T_400m</th>
<th>T_Sprnt</th>
<th>Tennis</th>
<th>W_Polo</th>
</tr>
</thead>
<tbody>
<tr>
<td>f</td>
<td>13</td>
<td>7</td>
<td>4</td>
<td>23</td>
<td>22</td>
<td>9</td>
<td>11</td>
<td>4</td>
<td>7</td>
<td>0</td>
</tr>
<tr>
<td>m</td>
<td>12</td>
<td>12</td>
<td>0</td>
<td>0</td>
<td>15</td>
<td>13</td>
<td>18</td>
<td>11</td>
<td>4</td>
<td>17</td>
</tr>
</tbody>
</table>

There are 202 athletes in total, all from the Australian Institute of Sport.

Figure 3.1 demonstrates the use of xyplot(). The plot is restricted to rowers and swimmers. The two panels distinguish the two sports, while different plotting symbols (on a color device, different colors will be used) distinguish females from males. Here is suitable code:

trellis.device(color=FALSE)
xyplot(ht ~ wt | sport, groups=sex, pch=c(4,1), aspect=1, data=ais,
       auto.key=list(columns=2), subset=sport%in%c("Row","Swim"))
dev.off()  # Close device
trellis.device()  # Start new device, by default with color=TRUE
3.1. LATTICE GRAPHICS

Figure 3.1: Height (ht) versus Weight (wt), for two categories of athlete. The different plotting symbols distinguish males from females.

In the graphics formula ht ~ wt | sport, the vertical bar indicates that what follows, in this case sport, is a conditioning variable or factor. The graphical information is broken down according to the factor levels or distinct values. The parameter aspect controls the ratio of dimensions in the y and x directions.

The setting auto.key=list(columns=2) generates a simple key, with the two key items side by side in two columns rather than one under another in a single column as happens with the default setting columns=1.

Selected lattice functions

<table>
<thead>
<tr>
<th>Function</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>dotplot(factor ~ numeric,...)</td>
<td># 1-dim. Display</td>
</tr>
<tr>
<td>stripplot(factor ~ numeric,...)</td>
<td># 1-dim. Display</td>
</tr>
<tr>
<td>barchart(character ~ numeric,...)</td>
<td></td>
</tr>
<tr>
<td>histogram(~ numeric,...)</td>
<td></td>
</tr>
<tr>
<td>densityplot(~ numeric,...)</td>
<td># Density plot</td>
</tr>
<tr>
<td>bwplot(factor ~ numeric,...)</td>
<td># Box and whisker plot</td>
</tr>
<tr>
<td>qqmath(factor ~ numeric,...)</td>
<td># normal probability plots</td>
</tr>
<tr>
<td>splom(~ dataframe,...)</td>
<td># Scatterplot matrix</td>
</tr>
<tr>
<td>parallel(~ dataframe,...)</td>
<td># Parallel coordinate plots</td>
</tr>
<tr>
<td>cloud(numeric ~ numeric * numeric,...)</td>
<td># 3D surface</td>
</tr>
<tr>
<td>wireframe(numeric ~ numeric * numeric,...)</td>
<td># 3D scatterplot</td>
</tr>
</tbody>
</table>

In each instance, users can add conditioning variables.

Further points to note about the lattice package are:

- Because the lattice package implements the trellis style of graphics, several of the functions that control stylistic features (color, plot characters, line type, etc.) have trellis (where lattice might have seemed more natural) as part of their name.

- Lattice graphics functions cannot be mixed (or not easily) with the graphics functions discussed earlier in Section 2.1.2. It is not possible to use points(), lines(), text(), etc., to add features to a plot that has been created using a lattice graphics function. Instead, it is necessary to use functions that are special to lattice – lpoints(), llines(), ltext(), larrows() and lsegments()
3.1.1 Groups within data, and/or columns in parallel

Here are selected lines from the data set `grog` (*DAAGxtras* package):

<table>
<thead>
<tr>
<th>Beer</th>
<th>Wine</th>
<th>Spirit</th>
<th>Country</th>
<th>Year</th>
</tr>
</thead>
<tbody>
<tr>
<td>1</td>
<td>2.86</td>
<td>1.81</td>
<td>Australia</td>
<td>1998</td>
</tr>
<tr>
<td>2</td>
<td>2.87</td>
<td>1.77</td>
<td>Australia</td>

<td>1.64</td>
<td>NewZealand</td>
<td>1999</td>
</tr>
<tr>
<td>18</td>
<td>3.09</td>
<td>2.20</td>
<td>NewZealand</td>
<td>2006</td>
</tr>
</tbody>
</table>

There are three liquor products (drinks), in different columns, and two countries, occupying different rows that are indexed by the factor `Country`. The function `xyplot()` can accommodate any of the following:

- Different symbols and/or colors, in the one panel, distinguish drinks. Different panels distinguish countries, as in Figure 3.2. If different countries are in the same panel, then drinks must be separated across different panels.
- Use a 3 drinks × 2 countries, or 2 countries × 3 drinks layout of panels.

Where plots are superposed in the one panel and, e.g., regression lines or smooth curves are fitted, this is done separately for each different set of points. Different colors, and/or by different symbols and/or line styles, can be used to make the necessary distinctions.

Code for Figure 3.2 is:

```r
## Simple version of plot
grogplot <- xyplot(Beer + Spirit + Wine ~ Year | Country, data=grog,
```

The data (dataset `grog`, from *DAAGxtras*) are 1998 – 2006 Australian and New Zealand apparent per person annual consumption (in liters) of the pure alcohol content. Data, based on Australian Bureau of Statistics and Statistics New Zealand figures, are obtained by dividing estimates of total available alcohol by number of persons aged 15 or more.
outer=FALSE, auto.key=list(columns=3))

## Enhance, and print enhanced code
update(grogplot, ylim=c(0,5.5),
     xlab="", ylab="Amount consumed (per person)",
     par.settings=simpleTheme(pch=c(1,3,4)))

The footnote\(^2\) has alternative code that updates the object, then uses an explicit print().

Observe that:

- Use of Beer+Spirit+Wine gives plots for each of Beer, Spirit and Wine. The effect of outer=FALSE is that these appear in the same panel.

- Conditioning by country (| Country) gives separate panels for separate countries.

- The function simpleTheme() sets up a “theme” that can be used to control point and line settings.

For separate panels for the three liquor products (different levels of Country can now use the same panel), specify outer=TRUE:

```
xyplot(Beer+Spirit+Wine ~ Year, groups=Country, outer=TRUE,
       data=grog, auto.key=list(columns=2))
```

Here is a summary:

<table>
<thead>
<tr>
<th>Overplot (a single panel)</th>
<th>Separate panels</th>
</tr>
</thead>
<tbody>
<tr>
<td>Break data down n/c to levels of the factor Country:</td>
<td></td>
</tr>
<tr>
<td>Beer ~ Year, groups=Country</td>
<td>Beer ~ Year</td>
</tr>
<tr>
<td>Plot columns in parallel, as in Beer+Wine+Spirit ~ Year:</td>
<td></td>
</tr>
<tr>
<td>outer=FALSE</td>
<td>outer=TRUE</td>
</tr>
</tbody>
</table>

### 3.1.2 Lattice Parameters and Graphics Features

Point, line and fill color settings, using simpleTheme()

The function simpleTheme() creates a “theme”, i.e., a list of parameter settings, in a form that can be supplied: (i) in the argument par.settings in the graphics function call; or (ii) in the argument theme in a call to trellis.par.set(), prior to calling the graphics function. A further possibility is to include an argument theme when using trellis.device() to start a new device. This has the default retain=FALSE, with the result that unless otherwise specified, parameters are reset to their defaults for the relevant device.

The following creates two “themes”:

```
settings1 <- simpleTheme(pch = c(1,3,4), cex=1.25)
ssettings2 <- simpleTheme(pch = c(1,3,4), alpha=0.5)
```

Use of settings1 may be appropriate when the number of points is small, while settings2 may be appropriate when there are many points and there is extensive over-plotting. Here, alpha controls the background transparency (c.f., also, alpha.points and alpha.line). Use of a value less than 1 helps in showing the density of points in regions where there is extensive overlapping.

The following gives the symbols and size of symbol used in Figure 3.2:

```r

## Update trellis object, then print
frillyplot <-
    update(grogplot, ylim=c(0,5.5), xlab="", ylab="Amount consumed (per person)",
           par.settings=simpleTheme(pch=c(1,3,4)))
print(frillyplot)
```
CHAPTER 3. LATTICE GRAPHICS

```r
grogplot0 <- xyplot(Beer+Spirit+Wine ~ Year | Country, outer=FALSE, 
data=grog, ylim=c(0,5.5))
grogplot <- update(grogplot0, par.settings=settings1)
print(grogplot)
```

The settings are stored as part of the graphics object `grogplot`.

Consider now the use of `trellis.par.set()` to change the settings globally, so that they remain in place until there is a further change or a new device is opened.

```r
trellis.par.set(settings2)
```

Then `print(grogplot)` will use `settings1` which are stored as part of the object, while `print(grogplot0)` will use the global `settings2`.

### 3.1.3 Setting that are not available using `simpleTheme()`

For changes that go beyond what `simpleTheme()` allows, it is necessary to know the names under which settings are stored. To inspect these, type:

```r
> names(trellis.par.get())
[1] "fontsize"      "background"    "clip"      
...                      
[28] "par.sub.text"
```

For a visual display that shows default settings for points, lines and fill colour, try the following:

```r
trellis.device(color=FALSE)
show.settings()
trellis.device(color=TRUE)
show.settings()
```

The following sets the fontsize. Notice the separate settings for text and symbols:

```r
trellis.par.set(list(fontsize = list(text = 7, points = 4)))
```

Parameters that affect axes, tick marks, and axis labels

These are readily manipulated by use of the `scales` argument to the lattice function. The following plots quarterly labor force numbers, in six regions of Canada, over 1995-1996. The code is:

```r
## Create a simplified version of the graphics object
jobs.xyplot <-
  xyplot(Ontario+Quebec+BC+Alberta+Prairies+Atlantic ~ Date, 
data=jobs, type="b", layout=c(3,2), ylab="Number of jobs", 
scales=list(y=list(relation="sliced", log=TRUE)), 
outer=TRUE)
## Update jobs.xyplot, with various enhancements
ylabpos <- exp(pretty(log(unlist(jobs[, -7])), 100))
ylabels <- paste(round(ylabpos), "\n", log(ylabpos), ",", sep="")
## Create a date object 'startofmonth'; use this instead of 'Date'
atdates <- seq(from=95, by=0.5, length=5)
datelabs <- format(seq(from=as.Date("1 Jan 1995", format="%d%b%Y"), 
by="6 month", length=5), "%b%y")
update(jobs.xyplot, xlab="", between=list(x=0.5, y=0.5), 
scales=list(x=list(at=atdates, labels=datelabs), 
y=list(at=ylabpos, labels=ylabels), tck=0.6))
```
The enhancements are:

- The $y$-axis labels show number of jobs, with log(number) in parentheses underneath.
- Dates of the form Jan95 label the $x$-axis.
- Tick marks are reduced in length ($tck=0.6$, i.e., 60% of the default).

Notice also the use of `between=list(x=0.5, y=0.5)` to add horizontal and vertical space between the panels, ensuring that the tick labels do not overlap.

### 3.1.4 Keys – auto.key, key & legend

The argument `auto.key=TRUE` gives a basic key that identifies colors, plotting symbols and names for the groups. For greater flexibility, `auto.key` can be a list. Settings that are often useful are:

- `points, lines`: in each case set to `TRUE` or `FALSE`.
- `columns`: number of columns of keys.
- `x` and `y`, which are coordinates with respect to the whole display area. Use these with `corner`, which is one of `c(0,0)` (bottom left corner of legend), `c(1,0)`, `c(1,1)` and `c(0,1)`.
- `space`: one of "top", "bottom", "left", "right".

Use of `auto.key` sets up the call `key=simpleKey()`. If not otherwise specified, colors, plotting symbols, and line type use the current trellis settings for the device. Unless the argument `text` is supplied, `levels(groups)` provides the legends. If necessary, use `legend=NULL` when updating, to remove an existing key and allow the addition of a different key.

### 3.1.5 Panel functions and interaction with plots

Each lattice command that creates a graph has its own panel function. Thus `xyplot()` has the panel function `panel.xyplot()`. The following are equivalent:

```r
yplot(ACT ~ year, data=austpop)
yplot(ACT ~ year, data=austpop, panel=panel.xyplot)
```

The user’s own function can be substituted for `panel.xyplot()`. Panel functions that may be used, either in combination with functions such as `panel.xyplot()` or separately, include:

- `panel.points()`, `panel.lines()` and a number of other such functions that are documented on the same help page as `panel.points()`;
- `panel.abline()`, `panel.curve()`, `panel.rug()`, `panel.average()` and a number of other functions that are documented on the same help page as `panel.abline()`.

### Interaction with lattice plots – the `playwith` package

For using `playwith`, the GTK+ toolkit must be installed. For details, go to the website [http://playwith.googlecode.com/](http://playwith.googlecode.com/).

For installing the `playwith` package type, from the command line:

```r
install.packages("playwith", dependencies=TRUE)
```

Now type, for example:

```r
library(DAAGxtras)
library(playwith)
playwith(xyplot(age ~ distance, data=hotspots), 
        labels=hotspots$name)
```
Plate 3.4 was then obtained as described in the figure caption.

An alternative is

```r
gph <- xyplot(age ~ distance, data=hotspots)
playwith(update(gph), labels=hotspots$name)
```

The menu that appears to the left of the graph can be used to initiate single click identification, to add annotation or arrows, or to mark out a rectangle on the graph for zooming in or out. If labels are not specified, row names are used.

Note also the function `latticist()` in the `latticist` package. When called with a data frame as argument, this opens a window that has graphical summary information on the columns of the data frame. Additionally, the window gives a graphical user interface to the creation of further lattice plots from the data frame. As when `playwith()` is used as a wrapper for a call to a lattice function, various annotation features are available.

### 3.1.6 Interaction with lattice plots – focus, interact, unfocus

As described here, interaction starts with the use of `trellis.focus()` to focus down to the relevant “viewport”, by default a panel. It may be called without arguments. If there is only one panel, it is then selected immediately. If there is more than one panel, the user chooses a panel by clicking on it.

Other choices of name include "panel", "strip", name="legend" and "toplevel". For name="legend"; side should be indicated.

#### Use of `panel.text()` to label points

Following a call to `trellis.focus()`, panel functions can be used to supplement plots. Use `trellis.panelArgs()` to extract arguments that are available to panel functions following such a call. The following adds text labels:

```r
xyplot(Brainwt ~ Bodywt, data=primates)
trellis.focus("panel", row=1, column=1, clip.off=TRUE,
highlight=FALSE)  # Non-interactive use
xyetc <- trellis.panelArgs()
panel.text( x=xyetc$x, y=xyetc$y, labels=row.names(primates), pos=3)
trellis.unfocus()
```

For non-interactive use, be sure to call `trellis.focus()` with the argument `highlight=FALSE`.

#### Use of `panel.identify()` to label points interactively

Here is an example of interactive labeling.

```r
## Use of `xyplot()`: data frame tinting (DAAG)
library(lattice)
xyplot(it ~ csoa | sex, data=tinting)
trellis.focus("panel", column=1, row=1)
` panel.identify(labels=as.character(tinting$target))
```

By default, the x and y arguments to the function `panel.identify()` are taken to be those that were supplied to the lattice function, here `xyplot()`.

Functions that may be called include `panel.lines()` and related functions, and `panel.abline()` and related functions, as described earlier.
3.1.7 Arbitrary placement of labels

The following uses the focus/unfocus mechanism to add to an existing graph:

```r
stripplot(species ~ length, xlab="", data=cuckoos)
trellis.focus(name="toplevel", highlight=FALSE)
panel.text("Stripplot of cuckoo data", x=0.05, y=0.95)
  # Here, x=0.05 translates to x=unit(0.05,"npc"); the range is (0,1)
trellis.unfocus()
```

The following uses the `grid` function `textGrob()` to create a text object which is then supplied to the lattice function:

```r
library(grid)
stripplot(species ~ length, xlab="", data=cuckoos,
  legend=list(top=list(fun=textGrob,
                      args=list(label="Stripplot", x=0))))
  # Here, x=0 is equivalent to x=unit(0,"npc"); the range is (0,1)
```

3.1.8 Multiple graphs on a single graphics page

Note first, for comparison, the use of the base graphics parameter `fig` to mark out a rectangular region where the graph will appear. For example:

```r
par(fig = c(0, 1, 0.38, 1)) # xleft, xright, ybottom, ytop
## Plot graph A
par(fig = c(0, 1, 0, 0.38), new=TRUE)
## Plot graph B
par(fig = c(0, 1, 0, 1) # Reset to default
```

The initial `par(fig = c(0, 1, 0.38, 1))` marks out a plot region that occupied the total width of the graphics page, started 38% of the way up, and extended to the top of the page. The subsequent `par(fig=c(0, 1, 0, 0.38), new=TRUE)` marked out the lower 38% of the page. The effect of `new=TRUE` is, counter-intuitively, “assume a new page is already open; do not open a new page”.

For lattice graphs, the location of the graph can be determined by the argument `position`, when `print()` is called. The following demonstrates its use:

```r
cuckoos.strip <- stripplot(species ~ length, xlab="", data=cuckoos)
print(cuckoos.strip, position=c(0,0.5,1,1))
  # xleft, ybottom, xright, ytop
cuckoos.bw <- bwplot(species ~ length, xlab="", data=cuckoos)
print(cuckoos.bw, position=c(0,0,1,0.5), newpage=FALSE)
```

Note the use of `newpage=FALSE` for the second plot.

Base and trellis plots on the same graphics page

The following uses the base graphics command `mtext()` to label a lattice plot:

```r
plot(0:1, 0:1, type="n", bty="n", axes=FALSE, xlab="", ylab="")
mtext(side=3, line=3, "Lattice bwplot (i.e., boxplot)
cuckoos.bw <- bwplot(species ~ length, data=cuckoos)
print(cuckoos.bw, newpage=FALSE)
```
3.1.9 Plots that Show Distributions

Stripplots, dotplots and boxplots

Because the syntax for `stripplot()` and `boxplot()` are very similar, we demonstrate suitable code side by side. (The function `dotplot()` is very similar to `stripplot()`, with differences that are mainly cosmetic.) The following code creates plots using the `cuckoos` data (from DAAG):

```r
stripplot(species ~ length, aspect=0.5, data=cuckoos, xlab="Cuckoo egg length (mm)")
bwplot(species ~ length, aspect=0.5, data=cuckoos, xlab="Cuckoo egg length (mm)")
```

The `aspect` argument determines the ratio of distance in the y-direction to distance in the x-direction.

Lattice Style Density Plots

Here is a density plot (Figure 3.3), for data from the `possum` data set (DAAG), that compares sexes and Vic/other populations.

```r
densityplot(~ earconch | sex, groups=Pop, data=possum, par.settings=simpleTheme(col=c("gray","black"), auto.key=list(columns=2))
```

Where `densityplot()` (and `histogram()`) have a formula as argument, a name is not allowed on the left of the `∼` symbol.

```
Vic -- other

Density

40 45 50 55

f

m

earconch
```

Figure 3.3: Lattice style density plot comparing possum earconch measurements, separately for males and females, between Victorian and other populations. Observe that the scatter of data values is shown along the horizontal axis.

Where `densityplot()` (and `histogram()`) have a formula as argument, a name is not allowed on the left of the `∼` symbol. For `histogram()`, which is otherwise similar to `densityplot()`, the `groups` argument is not available.

Further comments on Stripplots and Dotplots

Unless care is taken with the dimensions of the graphics page and/or the font size, labels for the levels of `yield` in the following plot will overlap.

```r
dotplot(variety ~ yield | site, data = barley, groups = year, xlab = "Barley Yield (bushels/acre) ", ylab = NULL, layout = c(1, 6), aspect = 0.5, auto.key=list(labels=levels(barley$year), space = "right"))
```

---

3 For slightly improved labeling, precede with:
levels(cuckoos$species) <- sub(",", "", levels(cuckoos$species), fixed=T)
Try stretching the plot vertically so that the labels do not overlap. The argument type="h") gives a line from the origin to the point. Both a line and a point may be given. This can be used to striking effect, as in the following:

```r
deathrate <- c(40.7, 36, 27, 30.5, 27.6, 83.5)
hosp <- c("Cliniques of Vienna (1834-63) (> 2000 cases pa)", 
"Enfans Trouves at Petersburg (1845-59, 1000-2000 cases pa)", 
"Pesth (500-1000 cases pa)", 
"Edinburgh (200-500 cases pa)", 
"Frankfort (100-200 cases pa)", "Lund (< 100 cases pa)")
hosp <- factor(hosp, levels=hosp[order(deathrate)])
dotplot(hosp ~ deathrate, xlim=c(0,110), cex=1.5, 
    scale=list(cex=1.25), type="h","p"), 
    xlab=list("Death rate per 1000 ", cex=1.5), 
    sub="From Nightingale (1871) - data from Dr Le Fort")
```

\[\text{Data are from Nightingale, F. (1871): Notes on Lying-in Institutions.}\]
Figure 3.4: This playwith GUI window was generated by wrapping the call to `xyplot()` in the function `playwith()`, then clicking on Identify. Click near to a point to see its label. A second click adds the label to the graph.
Chapter 4

The ggplot2 Package

This package, by Hadley Wickham, implements the graphics language that is described in Wilkinson’s Grammar of Graphics. A draft of Hadley Wickham’s book that describes the package is available from http://had.co.nz/ggplot2/. In contrast to base graphics, the syntax is consistent. It is much less stylized than lattice, and accordingly easier to adapt.

The examples that are given here will use the wrapper function qplot() (quickplot) that is designed for creating simple ggplot graphics objects. It has remarkably wide-ranging abilities.

4.1 Examples

Australian rain data

Figure 4.1 plots annual rainfall for South-East Australia.

Figure 4.1: Annual rainfall, from 1901 to 2008, for the Murray-Darling basin region of Australia. The curve is fitted using the default loess smoother. The pointwise standard error bands assume that errors about the curve are independent; this is unlikely to be strictly true. To suppress the bands, specify se=FALSE.

Here is the code.
library(DAAGxtras)
library(ggplot2)

## Default loess smooth, with SE bands added.
quickplot(Year, seRain, data=bomregions, geom=c("point","smooth"),
  span=0.1, xlab="", ylab="Av. rainfall, M-D basin")

Try also the following:

library(splines)
quickplot(Year, seRain, data=bomregions, geom=c("point","quantile"),
  formula = y ~ ns(x,5), quantiles=c(0.2,0.5,0.8))

The normal spline basis ns(x,5) is supplied to the function that fits the quantiles, so that 5 d.f. spline curves are fitted at the 20%, 50% and 80% quantiles.

Physical measurements of Australian athletes

Figure 4.2 plots height against weight, for the ais data. Boxplots that show the distributions of heights, and two-dimensional density contour estimates have been added. Figure 4.2 shows boxplots (geom="boxplot"), by sport (given as the x-variable) and sex (separate panels): The code is:

```
library(DAAGxtras)
library(ggplot2)

## Overlay scatterplots with boxplots and with density contours
quickplot(wt, ht, xlab="Weight (kg)", ylab="Height (cm)", data=ais,
  geom=c("boxplot","point","density2d"), facets = . ~ sex)
```

The facets argument takes the form row.var col.var, where row.var indexes the rows of panels, col.var indexes columns, and . is used as a placeholder when there is one row or one column only.

Try also:

```
## Two panels (columns): sexes have different colors and symbols
aisBS <- subset(ais, sport %in% c("Row","Swim"))
```
aisBS$sport <- factor(aisBS$sport)
quickplot(wt, ht, data=aisBS, type="point",
  colour=sex, shape=sex,
  facets = . ~ sport)
## Single panel: distinguish sexes by colors; sports by symbols
quickplot(wt, ht, data=aisBS, type="point",
  colour=sex, shape=sport)

To get different colours for different levels of sport, specify colour=sport. For different plotting symbols, specify shape=sport. For different sizes of symbol, specify size=sport. Two of these may appear together. For example:

quickplot(wt, ht, data=aisBS, type="point",
  colour=sex, shape=sex, size=I(2.5),
  facets = . ~ sport)
## Single panel: distinguish sexes by colors; sports by symbols
quickplot(wt, ht, data=aisBS, type="point",
  colour=sex, shape=sport, size=I(2.5))
## Single panel: distinguish sexes by colors; sports by symbol size
quickplot(wt, ht, data=aisBS, type="point",
  colour=sex, size=sport)

Possible choices of geom, additional to those already demonstrated, are "path" (join points), "line" (join points), "histogram", and "density".

Note the difference between:

size=I(2.5), used to make points somewhat larger than otherwise.

size=2.5, which specifies a mapping from the vector with the single element 2.5 to all points in the data. This does change the point size, but it adds adds an extraneous key. (This is analogous to the use of size=sport to specify a mapping from sport to size.)

Thus also, to make all points red, specify color=I("red"), not color="red"

Note also the following:

## Change the base pointsize for text to 8
theme_set(theme_gray(base_size=8))  # Gray theme
theme_set(theme_bw(base_size=8))    # Black and white theme
## Modify the pointsize
update_geom_defaults("point", aes(cex=1.25))

The function aes() generates aesthetic mappings. These map variables in the data to visual properties (aesthetics) of geoms.

Consult the web page [http://had.co.nz/ggplot/](http://had.co.nz/ggplot/) for up to date information on ggplot2.

### 4.2 Dynamic Graphics – the rgl package

This provides three-dimensional dynamic graphics. Try the following code. It uses functions in the Rcmdr package – scatter3d() and identify3d(). These may be more convenient for novices than the rgl functions that they call.

## The Rcmdr and rgl packages must be installed
library(Rcmdr)  # This makes scatter3d() available
## The call to open3d() is optional, but see below
open3d()
par3d(cex=0.6)  # Optional. Requires an rgl device to be open
with(nihills, scatter3d(x=log(dist), y=log(climb), z=log(time),
  type="point", cex=0.6))

```r
grid=FALSE, surface.col="gray",
point.col="black", axis.scales=FALSE)
with(nihills, identify3d(x=log(dist), y=log(climb), z=log(time),
labels=row.names(nihills), col="gray40"))
```

## NB: Use the middle or right mouse button to drag a rectangle around any pony that is to be labeled.

Following the call to `identify3d()`, use the middle (or maybe right) mouse button to drag a rectangle around any point that is to be labeled. To cease identifying points, make a middle (or right) click on an empty region of the plot. Use `rgl.snapshot()` to save the current plot into a file.
Chapter 5

References and Bibliography

5.1 Books and Papers on R

[An excellent R-based introductory statistics text]

(web page http://socserv.socsci.mcmaster.ca/jfox/Books/Companion/index.html)
[This is particularly aimed at classical types of regression calculations.]

[This is aimed at researchers who have had some previous exposure to statistics, and at applied statisticians.]

[This treats both R and S-PLUS.]

[This demands a relatively high level of sophistication. This treats both R and S-PLUS.]
