- The Complex Numbers

- The complex numbers \mathbb{C} form a plane.
- Their operations are very related to two dimensional geometry.
- ► In particular, multiplication by a unit complex number:

$$|z|^2 = 1$$

gives a rotation:

$$R_z(w) = zw.$$

- The Complex Numbers

Remember:

$$\blacktriangleright \mathbb{C} = \left\{ a + bi : a, b \in \mathbb{R}, \quad i^2 = -1 \right\}$$

- ► We can add and multiply in C.
- We can also conjugate:

$$\overline{a+bi}=a-bi.$$

And take norms:

$$|z|^2 = z\overline{z}$$

where

$$|a+bi|^2 = a^2 + b^2$$
.

This norm is crucial! It satisfies:

$$|zw|=|z||w|.$$

The Complex Numbers

The unit complex numbers

$$\mathrm{U}(1) = \left\{ z \in \mathbb{C} : |z|^2 = 1 \right\}$$

form a circle. They also form a group:

U(1) is closed under multiplication:

$$|zw| = |z||w| = 1$$

The conjugates are inverses:

$$|\overline{z}| = |z| = 1$$

and

$$z\overline{z} = |z|^2 = 1$$

-The Complex Numbers

The key group in plane geometry is SO(2), the group of rotations of the plane.

▶ We have a map

$$arphi: U(1) \rightarrow SO(2)$$

 $z \mapsto R_z$

This map is an isomorphism!

$$U(1) \cong SO(2).$$

◆□▶ ◆□▶ ▲□▶ ▲□▶ ▲□ ◆ ○○

So these groups are the same.

The 19th century Irish mathematician and physicist William Rowan Hamilton was fascinated by the role of \mathbb{C} in two-dimensional geometry.

For years, he tried to invent an algebra of "triplets" to play the same role in three dimenions:

$$a+bi+cj\in \mathbb{R}^3.$$

Alas, we now know this quest was in vain.

Theorem The only normed division algebras, which have a norm satisfying

|zw| = |z||w|

have dimension 1, 2, 4, or 8.

Hamilton's search continued into October, 1843:

Every morning in the early part of the above-cited month, on my coming down to breakfast, your (then) little brother William Edwin, and yourself, used to ask me: "Well, Papa, can you multiply triplets?" Whereto I was always obliged to reply, with a sad shake of the head: "No, I can only add and subtract them."

On October 16th, 1843, while walking with his wife in to a meeting of the Royal Society of Dublin, Hamilton discovered a 4-dimensional algebra called the **quaternions**:

That is to say, I then and there felt the galvanic circuit of thought close; and the sparks which fell from it were the fundamental equations between i, j, k; exactly such as I have used them ever since:

$$i^2 = j^2 = k^2 = ijk = -1.$$

The quaternions are

$$\mathbb{H} = \left\{ a + bi + cj + dk : a, b, c, d \in \mathbb{R} \right\}.$$

$$\flat ij = k = -ji.$$

▶ We can conjugate them:

$$\overline{a+bi+cj+dk}=a-bi-cj-dk.$$

There's a norm:

$$|q|^2 = q\overline{q}.$$

Satisfying:

$$|qu| = |q||u|$$

Just like the unit complex numbers, the unit quaternions form a group:

$$\operatorname{Spin}(3) = \left\{ q \in \mathbb{H} : |q|^2 = 1 \right\}$$

We can use these to give rotations in three dimensions!

• Think of \mathbb{R}^3 as the imaginary quaternions:

$$\operatorname{Im} \mathbb{H} = \{ ai + bj + ck : a, b, c \in \mathbb{R} \}$$

A unit quaternion gives a rotation:

$$R_q(\mathbf{v}) = q\mathbf{v}\overline{q}, \quad \mathbf{v} \in \operatorname{Im}\mathbb{H}.$$

- We can represent any rotation this way.
- This is often used in programming applications.
- We get a map:

$$arphi: ext{ Spin(3) } o ext{ SO(3) } \ q \quad \mapsto \quad R_q$$

where SO(3) is the group of rotations in three-dimensions.

◆□▶ ◆□▶ ▲□▶ ▲□▶ ▲□ ◆ ○○

Is this map an isomorphism?

No!

It's onto, but not 1-to-1:

$${\it R}_q = {\it R}_{-q}, ext{ since } q {f v} \overline{q} = (-q) {f v} (-\overline{q})$$

In fact, it's 2-to-1.

So, φ is not an isomorphism. Is there an isomorphism?

 $Spin(3) \cong SO(3)?$

We can answer this using topology.

As a space:

Spin(3) =
$$\{a + bi + cj + dk \in \mathbb{H} : a^2 + b^2 + c^2 + d^2 = 1\}$$

= S^3 .

(日) (日) (日) (日) (日) (日) (日)

the 3-sphere, a sphere of higher dimension.

SO(3) = ball of radius π with antipodal points identified.

These spaces sound different. Are they?

Yes!

- Spin(3) = S³ is simply connected: any loop in it can be continuously deformed to a point.
- SO(3) is not simply connected: there is a loop that can't be deformed to a point.

Therefore:

 $Spin(3) \not\cong SO(3).$

Amazingly, this fact is important in quantum physics!

A path from 0 to 360 in Spin(3) starts at 1, but ends at -1.

- Since $R_1 = R_{-1}$, this is OK.
- You must rotate from 0 to 720 to get back to 1.

Quantum mechanics says that particles are represented by waves:

The simplest kind of wave a is a function:

$$\psi \colon \mathbb{R} \to \mathbb{R}$$

But since we live in three dimensions:

$$\psi \colon \mathbb{R}^3 \to \mathbb{R}$$

And because it's quantum:

$$\psi \colon \mathbb{R}^3 \to \mathbb{C}$$

Yet, in 1924, Wolfgang Pauli (secretly) discovered that for electrons:

$$\psi \colon \mathbb{R}^3 \to \mathbb{H}$$

If we rotate most particles, we rotate its wave:

$$R_q\psi(\mathbf{v}):=\psi(R_{\overline{q}}(\mathbf{v})).$$

But to rotate an electron, Pauli found:

$${\sf R}_{{\sf q}}\psi({f v}):={\sf q}\psi({\sf R}_{\overline{{\sf q}}}({f v})).$$

In particular, for a 360 rotation:

$$R_{-1}\psi(\mathbf{v})=-\psi(\mathbf{v}).$$

◆□▶ ◆□▶ ▲□▶ ▲□▶ ▲□ ◆ ○○

Electrons can tell if they have been rotated 360!
