Framework

General framework:

Algorithms typically find a single interpretation of the data.

Alternative interpretations could exist.

Clustering framework:

Clustering is unsupervised classification and returns a set of clusters. What if prior knowledge is available?

- Alternative clustering(s) might be desirable.
- Semi-supervised methods.

Example – Automatic Lane Finding from GPS Traces

Where is the lane? [Wagstaff2001]

- Lane-level navigation (e.g. advance notification for taking exits).
- Lane-keeping suggestions (e.g. lane departure warning).

Constraints: width of a lane (maximum separation), points from the same vehicle end on the same lane if there are no lane changes (trace contiguity)

Example – Automatic Lane Finding from GPS Traces

Where is the lane? [Wagstaff2001]

- Lane-level navigation (e.g. advance notification for taking exits).
- Lane-keeping suggestions (e.g. lane departure warning).

Problem Description

Singular Alternative Clustering Problem

Given an objective function f, an existing clustering π so that $f(\pi) = x$, does there exist another clustering π' that is different from π and where $f(\pi') \approx f(\pi)$?

Key factors:

- Alternativeness
- Quality

Issues:

- Trade-off between alternativeness and quality of a new clustering.
- Retain certain clusters or chunklets?
- Alternative clustering just for a subspace of the data?

Algorithm-Independent Approach

Given: data $X = \{x_1, \ldots, x_n\} \subseteq \mathbb{R}^d$ and clustering $\pi = \{C_1, \ldots, C_k\}$ (with centroids m_j) found in X

Idea:

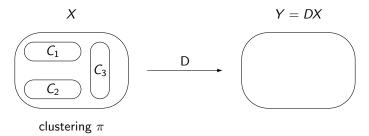

lacksquare transform X into new space Y with transformation matrix $D\in \mathbb{R}^{d imes d}$

• find a new clustering $\pi' = \{C'_1, \ldots, C'_k\}$ in Y

Solution to the Problem

Key factors:

- Quality: retain data properties \Rightarrow minimise Kullback-Leibler divergence between probability distributions of X and Y: $p_X(x), p_Y(y)$
- Alternativeness: properties from π to keep or not keep \Rightarrow constraints

Constraint Optimisation Problem $\min_{B \succeq 0} D_{KL}(p_Y(y)||p_X(x))$ s.t. $\frac{1}{n} \sum_{i=1}^n \sum_{j=1, x_i \notin C_j}^k ||x_i - m_j||_B^2 \le \beta$

where $B = D^T D$ and $||x - y||_B = \sqrt{(x - y)^T B(x - y)}$ (Mahalanobis distance).

Solution: $D = \tilde{\Sigma}^{-\frac{1}{2}}$ where $\tilde{\Sigma} = \frac{1}{n} \sum_{i=1}^{n} \sum_{j=1, x_i \notin C_j}^{k} (x_i - m_j) (x_i - m_j)^T$

Solution to the Problem

Key factors:

- Quality: retain data properties \Rightarrow minimise Kullback-Leibler divergence between probability distributions of X and Y: $p_X(x), p_Y(y)$
- Alternativeness: properties from π to keep or not keep \Rightarrow constraints

Constraint Optimisation Problem $\begin{array}{l} \min_{B \succeq 0} D_{\mathcal{K}L}(p_{Y}(y)||p_{X}(x)) \\ s.t. \ \frac{1}{n} \sum_{i=1}^{n} \sum_{j=1, x_{i} \notin C_{j}}^{k} ||x_{i} - m_{j}||_{B}^{2} \leq \beta \\ \end{array}$ where $B = D^{T}D$ and $||x - y||_{B} = \sqrt{(x - y)^{T}B(x - y)}$ (Mahalanobis distance). Solution: $D = \tilde{\Sigma}^{-\frac{1}{2}}$ where $\tilde{\Sigma} = \frac{1}{2} \sum_{i=1}^{n} \sum_{x_{i} \in C_{i}}^{k} |x_{i} - m_{j}||_{E}^{2} \leq \beta \\ \end{array}$

イロト 不得 トイヨト イヨト 二日

Solution to the Problem

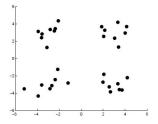

Key factors:

- *Quality:* retain data properties \Rightarrow minimise Kullback-Leibler divergence between probability distributions of X and Y: $p_X(x), p_Y(y)$
- Alternativeness: properties from π to keep or not keep \Rightarrow constraints

Constraint Optimisation Problem $$\begin{split} & \underset{B \succeq 0}{\min} D_{\mathcal{K}L}(p_Y(y)||p_X(x)) \\ & s.t. \ \frac{1}{n} \sum_{i=1}^n \sum_{j=1, x_i \notin C_j}^k ||x_i - m_j||_B^2 \leq \beta \end{split}$$ where $B = D^T D$ and $||x - y||_B = \sqrt{(x - y)^T B(x - y)}$ (Mahalanobis distance). Solution: $D = \tilde{\Sigma}^{-\frac{1}{2}}$ where $\tilde{\Sigma} = \frac{1}{n} \sum_{i=1}^n \sum_{j=1, x_i \notin C_j}^k (x_i - m_j)(x_i - m_j)^T$

くほと くほと くほと

Advantages:

- Algorithm-independent and easy to implement (closed-form solution).
- Trade-off between alternativeness and quality can be controlled.
- Easy to specify what properties of a given clusterings to keep or not keep.
- Distance matrix can be used in any distance-based method (cp. ordination methods with distance metrics).
- Approach can be used along with ordination methods in order to analyse classification methods (e.g. reveal additional classes or misclassified points).

프 에 에 프 어

Disadvantages:

- Algorithm-independent approach, i.e. the approach inherits the drawbacks of the algorithm used,
 - e.g. k-means: efficient, but it is sensitive to outliers, it often terminates at a local optimum and an inappropriate choice of k may yield poor results.
- Assumptions: clusters in π' are multivariate Gaussian, same cluster sizes, constant variances, dimensions highly independent,...
- Sometimes a non-linear transformation might be more appropriate (~→ future work).
- Approach is very general; special algorithms such as COP k-means might be more efficient [Wagstaff2001].
- Expert guidance becomes impractical in very large datasets.

- Approach is very general; special algorithms such as COP k-means might be more efficient [Wagstaff2001].
- Expert guidance becomes impractical in very large datasets.

Disadvantages:

- Algorithm-independent approach, i.e. the approach inherits the drawbacks of the algorithm used,
 - e.g. k-means: efficient, but it is sensitive to outliers, it often terminates at a local optimum and an inappropriate choice of k may yield poor results.
- Assumptions: clusters in π' are multivariate Gaussian, same cluster sizes, constant variances, dimensions highly independent,...
- Sometimes a non-linear transformation might be more appropriate (~→ future work).
- Approach is very general; special algorithms such as COP k-means might be more efficient [Wagstaff2001].
- Expert guidance becomes impractical in very large datasets.

Variations of the Constrained Optimisation Problem

Specifiying the trade-off between alternativeness and quality: *New constraint:*

$$\frac{1}{n}\sum_{i=1}^{n}\sum_{j=1,x_i\notin C_j}^{k}||x_i - m_j||_B^{\alpha} \leq \beta \text{ where } \alpha \geq 1$$

 $\alpha \uparrow \Rightarrow \mathsf{alternativeness} \uparrow$

Specifiying which clusters to keep and not keep:

- Retain cluster C_{ρ} : $\sum_{x_i \in C_{\rho}} ||x_i m_{\rho}||_B^2 \le \delta$ with δ small
- Retain clusters C_Y = {C₁,..., C_r} (1 < r < k): New constraint:

$$\sum_{\mathbf{x}_{i} \in C_{\mathbf{Y}}} \sum_{p=1, x_{i} \in C_{p}}^{r} ||x_{i} - m_{p}||_{B}^{2} + \sum_{\mathbf{x}_{i} \notin C_{\mathbf{Y}}} \sum_{j=1, x_{i} \notin C_{j}}^{k} ||x_{i} - m_{j}||_{B}^{2} \leq \beta$$
