

A new twist of the Carleson operator

Po-Lam Yung

University of Oxford

July 16, 2014

Introduction

- ▶ Joint work with Lillian Pierce
- ▶ Our main theorem concerns a variant of the Carleson operator, which was first studied in relation to pointwise a.e. convergence of Fourier series.
- ▶ Part 1: Introduction, and statement of our main theorem
- ▶ Part 2: A taste of time-frequency analysis
- ▶ Part 3: Some aspects of the proof of our main theorem

Part 1: Introduction, and statement of our main theorem

Motivation: Pointwise a.e. convergence of Fourier series

- ▶ Given an integrable function f on $[0, 1]$, we associate to f its Fourier series

$$\sum_{n=-\infty}^{\infty} \widehat{f}(n) e^{2\pi i n x},$$

where

$$\widehat{f}(n) := \int_0^1 f(x) e^{-2\pi i n x} dx.$$

- ▶ Fourier had the insight that perhaps “every” function can be expanded as its Fourier series.
- ▶ It took mathematicians quite some time to clarify and make precise this claim of Fourier.

- ▶ Let

$$S_N f(x) = \sum_{n=-N}^N \widehat{f}(n) e^{2\pi i n x}.$$

- ▶ If f is C^α for some $\alpha > 0$, then

$$S_N f(x) \rightarrow f(x) \quad \text{for every } x \in [0, 1].$$

The corresponding result is false if f is merely continuous.

- ▶ If f is in L^p , $1 < p < \infty$, then

$$S_N f \rightarrow f \quad \text{in } L^p \text{ norm.}$$

The corresponding result is false if $p = 1$.

- ▶ Things can go really wrong with L^1 : there exist L^1 functions whose Fourier series diverges everywhere.
- ▶ Question: what if one is only interested in almost everywhere convergence of Fourier series?

- ▶ Theorem (Carleson 1966, Hunt 1967):

If f is in L^p , $1 < p < \infty$, then

$$S_N f(x) \rightarrow f(x) \quad \text{for almost every } x \in [0, 1].$$

- ▶ The proof proceeds via approximating a function in L^p by smooth functions.
- ▶ The key then is to control a certain maximal operator, which has since been called the Carleson operator:

$$f(x) \mapsto \sup_{N \in \mathbb{N}} |S_N f(x)|.$$

This operator maps L^p boundedly into L^p , for all $1 < p < \infty$.
($p = 2$: Carleson's theorem; other values of p : result of Hunt)

- ▶ Later C. Fefferman (1973) and Lacey-Thiele (2000) gave very interesting alternative proofs. The techniques developed have since evolved into a field called *time-frequency analysis*.

A variant on \mathbb{R}^n

- ▶ If we are given instead an L^p function f on \mathbb{R} , we could also ask whether

$$\int_{-N}^N \widehat{f}(\xi) e^{2\pi i x \xi} d\xi$$

converges to $f(x)$ for almost every $x \in \mathbb{R}$.

- ▶ This would require one to study the operator

$$f(x) \mapsto \sup_{N>0} \left| \int_{-N}^N \widehat{f}(\xi) e^{2\pi i x \xi} d\xi \right|.$$

- ▶ Modulo some trivial operators, one has then to bound the operator

$$f(x) \mapsto \sup_{\lambda \in \mathbb{R}} \left| \text{p.v.} \int_{\mathbb{R}} f(x-y) \frac{1}{y} e^{2\pi i \lambda y} dy \right|.$$

- ▶ Note $\text{p.v.} \frac{1}{y}$ is the simplest Calderon-Zygmund kernel on \mathbb{R} .

- ▶ More precisely, by a Calderon-Zygmund kernel on \mathbb{R}^n , we mean a distribution K that agrees with a smooth function $K_0(y)$ outside the origin, with

$$|K_0(y)| \leq C|y|^{-n}, \quad |\nabla^\alpha K_0(y)| \leq C|y|^{-(n+|\alpha|)}, \quad \widehat{K} \in L^\infty.$$

- ▶ e.g. $K = \text{p.v.} \frac{y_j}{|y|^{n+1}}$ on \mathbb{R}^n .
- ▶ Sjölin formulated a version of Carleson's operator on \mathbb{R}^n . It is given by

$$Cf(x) := \sup_{\lambda \in \mathbb{R}^n} \left| \int_{\mathbb{R}^n} f(x-y)K(y)e^{i\lambda \cdot y} dy \right|,$$

where $K(y)$ is a fixed Calderon-Zygmund kernel on \mathbb{R}^n .

- ▶ **Theorem (Sjölin):** $C: L^p \rightarrow L^p$, for all $1 < p < \infty$.

A variant with polynomial phases

- ▶ Stein-Wainger (2001) initiated the study of a variant of the Carleson operator, where the phase $\lambda \cdot y$ in the exponential $e^{i\lambda \cdot y}$ is replaced by a real polynomial of higher degree in y .
- ▶ More precisely, let \mathcal{P}_d be the set of all real polynomials of degrees $\leq d$ on \mathbb{R}^n , and \mathcal{P}'_d be the set of all polynomials in \mathcal{P}_d that vanishes at the origin to order ≥ 2 . Define

$$C_d f(x) = \sup_{P \in \mathcal{P}'_d} \left| \int_{\mathbb{R}^n} f(x-y) K(y) e^{iP(y)} dy \right|.$$

Then Stein-Wainger proved that $C_d: L^p(\mathbb{R}^n) \rightarrow L^p(\mathbb{R}^n)$ for all $1 < p < \infty$ and all d , using stationary phases.

- ▶ This does not cover the Carleson's Theorem stated above; later, using time-frequency analysis, Lie (2009) improved Stein-Wainger's result when $n = 1$ by replacing \mathcal{P}'_d by the bigger class \mathcal{P}_d , thereby obtaining a true generalization of Carleson's Theorem.

A variant with Radon transform

- ▶ In joint work with Lillian Pierce, we study a variant of the theorem of Stein-Wainger, where an additional Radon transform is involved. For concreteness, we will work with the Radon transform along the paraboloid in \mathbb{R}^3 .
- ▶ Recall that if $K(y)$ is a Calderon-Zygmund kernel on \mathbb{R}^2 , then given a function $f(x, t)$ on \mathbb{R}^3 , where $x \in \mathbb{R}^2$ and $t \in \mathbb{R}$, the singular Radon transform of f along the paraboloid is given by

$$Rf(x, t) := \int_{\mathbb{R}^2} f(x - y, t - |y|^2)K(y)dy.$$

- ▶ The operator we study takes the form

$$\mathfrak{C}_d f(x, t) := \sup_{P \in \mathcal{Q}'_d} \left| \int_{\mathbb{R}^2} f(x - y, t - |y|^2)K(y)e^{iP(y)} dy \right|,$$

where \mathcal{Q}'_d is a class of polynomials of degree $\leq d$ on \mathbb{R}^2 to be specified.

- ▶ More precisely, fix a positive integer $d \geq 2$.

For $2 \leq j \leq d$, fix some polynomial $p_j(y)$ on \mathbb{R}^2 , that is homogeneous of degree j , and that has real coefficients.

Let $\mathcal{Q}'_d = \left\{ \sum_{j=2}^d \lambda_j p_j(y) : \lambda_j \in \mathbb{R} \text{ for all } j \right\} \subset \mathcal{P}'_d$

$K(y)$ = a Calderon-Zygmund kernel on \mathbb{R}^2

Theorem 1 (Pierce-Y.)

If $p_2(y) \not\equiv C|y|^2$ for any non-zero constant C , then the operator

$$\mathfrak{C}_d f(x, t) := \sup_{P \in \mathcal{Q}'_d} \left| \int_{\mathbb{R}^2} f(x - y, t - |y|^2) K(y) e^{iP(y)} dy \right|$$

is bounded on $L^p(\mathbb{R}^3)$ for $1 < p < \infty$ and all d .

Part 2: A taste of time-frequency analysis

Heuristics of the Proof of Carleson's theorem

- ▶ Let

$$H_N f(x) = \sum_{n>N} \widehat{f}(n) e^{2\pi i n x},$$

$$\mathcal{C}f(x) = \sup_{N \geq 0} |H_N f(x)|.$$

- ▶ Then the original theorem of Carleson is equivalent to the statement that

$$\mathcal{C}: L^2 \rightarrow \text{weak-}L^2.$$

- ▶ Let's first understand $H_N f$.
- ▶ Step 1: an orthogonal decomposition in frequency space
- ▶ Step 2: an orthogonal decomposition in the physical space.

A first decomposition: decomposition in frequency space

- ▶ A dyadic interval is an interval of the form $[(m-1)2^k, m2^k)$ for some integers m and k .
- ▶ For each fixed k , the dyadic intervals of length 2^k tile the real axis.

- ▶ Each dyadic interval ω has a parent ω^* , which is the unique dyadic interval that contains ω , and has twice the length of ω .
- ▶ Given any integer $N \geq 0$, one can decompose $[N + 1, \infty)$ into a disjoint union of dyadic intervals:

$$[N + 1, \infty) = \bigcup_{k=0}^{\infty} \omega_{k,N}$$

where each $\omega_{k,N}$ is either an empty set, or a dyadic interval of length 2^k with $\omega_{k,N}^* \not\subset [N + 1, \infty)$.

- ▶ Examples

Decomposition of $[N + 1, \infty)$

$N = 0$

$N = 4$

- ▶ Let

$$\Pi_{\omega_k, N} f(x) = \sum_{n \in \omega_k, N} \hat{f}(n) e^{2\pi i n x}.$$

- ▶ Then

$$H_N f = \sum_{k=0}^{\infty} \Pi_{\omega_k, N} f.$$

- ▶ It is now helpful to draw a picture of the *time-frequency* plane (or the x - n plane), to illustrate where (morally speaking) each term is supported.

$$H_0 f = \sum_{k=0}^{\infty} \Pi_{\omega_{k,0}} f,$$

$$H_4 f = \sum_{k=0}^{\infty} \Pi_{\omega_{k,4}} f.$$

A second decomposition: decomposition in physical space

- ▶ For $k \geq 0$, $\ell = 1, \dots, 2^k$, let $I_{k,\ell} = [(\ell - 1)2^{-k}, \ell 2^{-k})$, so that

$$[0, 1) = \bigcup_{\ell=1}^{2^k} I_{k,\ell}.$$

Also let

$$\psi_{k,\ell} = 2^{k/2} \chi_{I_{k,\ell}}(x).$$

Then since $\Pi_{\omega_{k,N}} f$ is roughly constant on a physical scale 2^{-k} ,

$$\Pi_{\omega_{k,N}} f \simeq \sum_{\ell=1}^{2^k} \langle \Pi_{\omega_{k,N}} f, \psi_{k,\ell} \rangle \psi_{k,\ell} \simeq \sum_{\ell=1}^{2^k} \langle f, \Pi_{\omega_{k,N}} \psi_{k,\ell} \rangle \Pi_{\omega_{k,N}} \psi_{k,\ell},$$

so that

$$H_N f \simeq \sum_{k=0}^{\infty} \sum_{\ell=1}^{2^k} \langle f, \Pi_{\omega_{k,N}} \psi_{k,\ell} \rangle \Pi_{\omega_{k,N}} \psi_{k,\ell}.$$

$$H_N f \simeq \sum_{k=0}^{\infty} \sum_{l=1}^{2^k} \langle f, \Pi_{\omega_{k,N}} \psi_{k,l} \rangle \Pi_{\omega_{k,N}} \psi_{k,l}.$$

$N = 0$

$N = 4$

- ▶ A tile is a dyadic rectangle (i.e. a product of two dyadic intervals) in the time-frequency plane with area 1.
- ▶ We just saw that $H_N f$ is essentially a sum over tiles; essentially any tile could arise in the decomposition of $H_N f$ for a suitable N .
- ▶ Therefore analyzing the Carleson operator

$$Cf(x) = \sup_{N \geq 0} |H_N f(x)|$$

forces one to consider essentially the set of all tiles in the time-frequency plane.

- ▶ But that is a lot of tiles!
- ▶ For each $k \in \mathbb{N}$, the set of tiles whose dimensions are $2^k \times 2^{-k}$ tile the time-frequency plane:

Tiling with tiles of sizes $2^{-k} \times 2^k$

$k = 1$

$k = 2$

$k = 3$

- ▶ Fortunately, not all tiles contribute, and one can organize the ones that contribute into unions of trees.
- ▶ The Carleson operator is then a sum over trees, and each tree would give rise to an operator that is like the Hilbert transform, that is bounded on any L^p .
- ▶ The key is then to exhibit orthogonality between operators corresponding to different trees, so as to prove that the full Carleson operator is weak-type (p, p) .
- ▶ Carleson, Fefferman, and Lacey and Thiele each has a different way of exhibiting this crucial orthogonality; we will not enter into details here.

- ▶ On the other hand, Stein and Wainger's approach to their theorem does not require the use of all this machinery from time-frequency analysis.
- ▶ Instead, it is based on a simple, but very clever observation, that allows them to exploit the additional oscillations they have in the polynomial phases they consider.
- ▶ Our approach to our main theorem is a refinement of that, to take into account the presence of a Radon transform along the paraboloid.

Part 3: Some aspects of proof of our main theorem

Proof of our main Theorem 1

- ▶ Recall our polynomial Carleson operator along the paraboloid:

$$\mathfrak{C}_d f(x, t) := \sup_{P \in \mathcal{Q}'_d} \left| \int_{\mathbb{R}^2} f(x - y, t - |y|^2) K(y) e^{iP(y)} dy \right|.$$

- ▶ We want to prove that it is bounded on $L^2(\mathbb{R}^3)$.
- ▶ Proof uses the method of stationary phases (rather than time-frequency analysis).
- ▶ In fact, when $|y|$ is small, $e^{iP(y)} \simeq 1$. This suggests that one should decompose $K(y)$ dyadically:

$$K(y) = \sum_{k=-\infty}^{\infty} 2^{-2k} \eta^{(k)}(2^{-k}y),$$

and estimate the terms with small k (say $k \leq k(P)$) with a maximal truncated singular Radon transform.

- ▶ Thus we are reduced to the terms with k large:

k large → Integrating over large values of $|y|$
→ The phase $P(y)$ oscillates rapidly
→ Decay in k

This then allows us to sum over large k in the previous slide, and prove our main theorem.

- ▶ Notation: If P is a polynomial in y , say

$$P(y) = \sum_{0 \leq |\alpha| \leq d} \lambda_\alpha y^\alpha,$$

then the isotropic norm of P is defined by

$$\|P\| = \sum_{|\alpha| \geq 1} |\lambda_\alpha|.$$

Theorem 2 (Pierce-Y.)

Let η be a C^1 function supported in the unit ball, and $d \in \mathbb{N}$. For each polynomial $P \in \mathcal{Q}'_d$ and each $k \in \mathbb{Z}$, define

$$\mathcal{I}_k^P f(x, t) = \int_{\mathbb{R}^2} f(x - y, t - |y|^2) 2^{-2k} \eta(2^{-k} y) e^{iP(2^{-k} y)} dy.$$

Then there is some $\delta_0 > 0$ such that for all $r \geq 1$, the operator

$$M_r f(x, t) := \sup_{k \in \mathbb{Z}} \sup_{\substack{P \in \mathcal{Q}'_d \\ \|P\| \simeq r}} |\mathcal{I}_k^P f(x, t)|$$

is bounded on $L^2(\mathbb{R}^3)$ with norm $\lesssim r^{-\delta_0}$.

- ▶ Since M_r is pointwisely bounded by the maximal Radon transform of f , it is certainly bounded on L^2 . The key here is the decay in r of the norm of the operator when r is large.

A toy model for Theorem 2

- ▶ To illustrate our method and to understand some of the difficulties involved, we consider the following toy problem.
- ▶ Let's fix $k = 0$ and consider

$$M_{r,0}f(x, t) := \sup_{\substack{P \in Q'_d \\ \|P\| \simeq r}} |\mathcal{I}_0^P f(x, t)|.$$

Proposition (Pierce-Y.)

There exists $\delta > 0$ such that for all $r \geq 1$, $M_{r,0}$ is bounded on $L^2(\mathbb{R}^3)$, with norm $\lesssim r^{-\delta}$.

- ▶ Again the key is to gain the decay in r of the norm of the operator. To do so we use stopping times and TT^* .

- ▶ Recall $M_{r,0}f(x, t) = \sup_P |\mathcal{I}_0^P f(x, t)|$.
- ▶ At each point (x, t) , this supremum is almost attained at a possibly different polynomial P , say $P_{(x,t)}$.
- ▶ Consider the linear operator

$$Tf(x, t) := \mathcal{I}_0^{P_{(x,t)}} f(x, t).$$

It suffices to show that T is bounded on L^2 with norm $\lesssim r^{-\delta}$.

- ▶ Since T is linear, it suffices to prove that TT^* is bounded on L^2 , with norm $\lesssim r^{-2\delta}$. This is desirable since the kernel of TT^* exhibits more cancellation than that of T :

- ▶ In fact,

$$Tf(x, t) = \int_{\mathbb{R}^2} f(x - y, t - |y|^2) \eta(y) e^{iP_{(x,t)}(y)} dy$$

$$T^*f(x, t) = \int_{\mathbb{R}^2} f(x + z, t + |z|^2) \eta(z) e^{iP_{(x+z, t+|z|^2)}(z)} dz$$

so $TT^*f(x, t)$ is given as an integral over 4-dimensions.

- ▶ One can then (almost) write $TT^*f(x, t)$ as a 3-dimensional convolution against a convolution kernel; the kernel will then be a 1-dimensional (oscillatory) integral.
- ▶ In fact,

$$TT^*f(x, t) = \int_{\mathbb{R}^2 \times \mathbb{R}} f(x - u, t - |u|^2 - 2|u|\tau) K_{P_1, P_2}^\sharp(u, \tau) dud\tau,$$

for a suitable kernel K_{P_1, P_2}^\sharp , where

$$P_1 := P_{(x,t)}, \quad P_2 := P_{(x-u, t-|u|^2-2|u|\tau)}.$$

- ▶ The kernel K_{P_1, P_2}^\sharp is defined in terms of an oscillatory integral:

$$K_{P_1, P_2}^\sharp(u, \tau) := \int_{\mathbb{R}} e^{iP_1(u+z) - iP_2(z)} \eta(u+z) \eta(z) d\sigma,$$

where $z = (z_1, z_2)$ is defined by $z_1 = \frac{u_1 \tau + u_2 \sigma}{|u|}$, $z_2 = \frac{u_2 \tau - u_1 \sigma}{|u|}$.

- ▶ Note that while $Tf(x, t)$ is given as an integral over 2 dimensions, the kernel K_{P_1, P_2}^\sharp is only a 1-dimensional integral.
 - Less oscillations in the integral defining K_{P_1, P_2}^\sharp
 - so method of TT^* is less effective in the Radon case.
- ▶ But we still hope to gain something non-trivial from the oscillatory nature of the integral defining K_{P_1, P_2}^\sharp .

- ▶ First we have a trivial bound:

$$|K_{P_1, P_2}^\#(u, \tau)| \lesssim 1, \text{ and is supported where } |u|, |\tau| \lesssim 1.$$

- ▶ As a result,

$$|TT^*f(x, t)| \lesssim \int_{\mathbb{R}^2 \times \mathbb{R}} |f|(x - u, t - |u|^2 - 2|u|\tau) \chi_{B_1}(u) \chi_{B_1}(\tau) du d\tau$$

which is bounded on L^2 with norm $\lesssim 1$; we need to do better.

- ▶ Using the method of stationary phases, we improve the above trivial bound on $K_{P_1, P_2}^\#$.

(It is only here that we use our assumption that our polynomial phases $P(y)$ are from our specific class \mathcal{Q}'_d .)

Lemma

If $P_1, P_2 \in \mathcal{Q}'_d$ with $\|P_1\|, \|P_2\| \simeq r$, then there exists

- ▶ some $\delta > 0$ depending only on d ,
- ▶ a set $E(P_1)$ depending only on P_1 , and
- ▶ a family of sets $F(P_1, u)$ depending only on P_1 and u ,

such that

$$|K_{P_1, P_2}^\#(u, \tau)| \lesssim r^{-2\delta} \chi_{B_1}(u) \chi_{B_1}(\tau) + \chi_{E(P_1)}(u) \chi_{B_1}(\tau) + \chi_{B_1}(u) \chi_{F(P_1, u)}(\tau).$$

Furthermore, the sets $E(P_1)$ and $F(P_1, u)$ has small measures:

$$|E(P_1)| \lesssim r^{-8\delta}, \quad \text{and} \quad |F(P_1, u)| \lesssim r^{-8\delta} \quad \text{for all } u.$$

- ▶ Then we have the following bound for $|TT^*f(x, t)|$:

$$\int_{\mathbb{R}^2 \times \mathbb{R}} |f|(x - u, t - |u|^2 - 2|u|\tau) \left[r^{-2\delta} \chi_{B_1}(u) \chi_{B_1}(\tau) + \chi_{E(P_{(x,t)})}(u) \chi_{B_1}(\tau) + \chi_{B_1}(u) \chi_{F(P_{(x,t),u})}(\tau) \right] dud\tau.$$

- ▶ This is a sum of three terms, and they are all bounded on L^2 with a small norm $\lesssim r^{-2\delta}$ (e.g. by interpolation between a good $L^\infty \rightarrow L^\infty$ bound, and a trivial $L^1 \rightarrow L^1$ bound).
- ▶ It is important here that we get small exceptional sets $E(P_1)$ and $F(P_1, u)$ that are independent of P_2 : otherwise we then need to estimate things like

$$\int_{\mathbb{R}^2 \times \mathbb{R}} |f|(x - u, t - |u|^2 - 2|u|\tau) \chi_{E(P_{(x,t), P_{(x-u, t-|u|^2-2|u|\tau)})}(u) \chi_{B_1}(\tau) dud\tau,$$

which we cannot quite estimate.

Back to Theorem 2: bounding a square function

- ▶ At this point, we observe that if one wants to apply the same argument to prove the desired bound for our original operator

$$M_r f(x, t) = \sup_k \sup_P |\mathcal{I}_k^P f(x, t)|,$$

one would naively also adopt a stopping time in k , and do a TT^* , because otherwise one does not have a linear operator T , and linearity is crucial for the application of TT^* .

- ▶ Unfortunately, stopping times and the method of TT^* are not good for bounding the supremum in k , as is known when people tried to bound the (ordinary) maximal Radon transform along the paraboloid.
- ▶ So we proceed differently, by introducing a smoother variant of our maximal operator, and estimating a square function.

- ▶ Recall that our operator M_r is given by

$$M_r f(x, t) = \sup_k \sup_P |\mathcal{I}_k^P f(x, t)|,$$

$$\mathcal{I}_k^P f(x, t) = \int_{\mathbb{R}^2} f(x - y, t - |y|^2) e^{iP(\frac{y}{2^k})} \eta\left(\frac{y}{2^k}\right) \frac{dy ds}{2^{2k}}.$$

- ▶ The key is to compare $\mathcal{I}_k^P f(x, t)$ to a smoother variant, which we call $\mathcal{J}_k^P f(x, t)$.
- ▶ Let now $\zeta \in C_c^\infty[-1, 1]$ be fixed, with $\int_{\mathbb{R}} \zeta(s) ds = 1$. Define

$$\mathcal{J}_k^P f(x, t) := \int \int_{\mathbb{R}^2 \times \mathbb{R}} f(x - y, t - s) e^{iP(\frac{y}{2^k})} \eta\left(\frac{y}{2^k}\right) \zeta\left(\frac{s}{2^{2k}}\right) \frac{dy ds}{2^{4k}}.$$

- ▶ Note an important cancellation property between \mathcal{I}_k^P and \mathcal{J}_k^P :

$$\int_{\mathbb{R}} (\mathcal{I}_k^P - \mathcal{J}_k^P) f(x, t) dt = 0 \quad \text{for every } x.$$

► Now

$$\begin{aligned} M_r f &= \sup_k \sup_P |\mathcal{I}_k^P f| \\ &\leq \sup_k \sup_P |\mathcal{J}_k^P f| + \sup_k \sup_P |(\mathcal{I}_k^P - \mathcal{J}_k^P) f| \\ &\leq \sup_k \sup_P |\mathcal{J}_k^P f| + \left(\sum_{k \in \mathbb{Z}} \sup_P |(\mathcal{I}_k^P - \mathcal{J}_k^P) f|^2 \right)^{1/2}. \end{aligned}$$

- The first term is known to be bounded on L^2 with norm $\lesssim r^{-2\delta}$, by an easy modification of Stein and Wainger's argument. (No Radon behavior for \mathcal{J}_k^P !)
- Thus to show that M_r is bounded on L^2 with the desired norm, it suffices to prove the same for the second term:

$$S_r f(x, t) := \left(\sum_{k \in \mathbb{Z}} \sup_{\substack{P \in \mathcal{Q}'_d \\ \|P\| \simeq r}} |(\mathcal{I}_k^P - \mathcal{J}_k^P) f(x, t)|^2 \right)^{1/2}.$$

- ▶ Square function again:

$$S_r f(x, t) := \left(\sum_{k \in \mathbb{Z}} \sup_P |(\mathcal{I}_k^P - \mathcal{J}_k^P) f(x, t)|^2 \right)^{1/2}.$$

- ▶ Recall that $\mathcal{I}_k^P - \mathcal{J}_k^P$ satisfies a cancellation property
→ Morally speaking, $\mathcal{I}_k^P - \mathcal{J}_k^P$ should act only on the part of f with 'frequency' $\simeq 2^{-k}$.
- ▶ So by decomposing f in the 'frequency' space, one can hope to carry out the sum in k in the definition of S_r .
- ▶ More precisely, we hope to be able to find Littlewood-Paley projections Δ_j , such that one can decompose any $f \in L^2(\mathbb{R}^3)$ as

$$f = \sum_{j \in \mathbb{Z}} \Delta_j F_j, \quad \sum_{j \in \mathbb{Z}} \|F_j\|_{L^2}^2 \lesssim \|f\|_{L^2}^2,$$

and $\Delta_j f$ has 'frequency' 2^{-j} .

- ▶ More importantly, we hope to choose Littlewood-Paley projections Δ_j , such that the following holds:

Theorem 3 (Pierce-Y.)

There exists $\delta_0 > 0$ and $\varepsilon_0 > 0$ such that for all $r \geq 1$ and $j, k \in \mathbb{Z}$,

$$M_{r,j,k} f(x, t) := \sup_{\substack{P \in Q'_d \\ \|P\| \simeq r}} |(\mathcal{I}_k^P - \mathcal{J}_k^P) \Delta_j f(x, t)|$$

is bounded on $L^2(\mathbb{R}^3)$, with norm $\lesssim 2^{-\varepsilon_0|j-k|} r^{-\delta_0}$.

- ▶ Note the additional decay when $|j - k|$ is large.
- ▶ When $2^{-j} \leq 2^{-k}$, use the cancellation property of $\mathcal{I}_k^P - \mathcal{J}_k^P$;
- ▶ When $2^{-j} > 2^{-k}$, one needs a cancellation property from Δ_j .

► The question now is then two-fold, namely:

(1) What cancellation property do we require of Δ_j ?

(2) How can we exploit that cancellation property?

► The answer to the first question has a nice simple form:
We just take Δ_j to be a Littlewood-Paley projection in the last variable:

$$\Delta_j f(x, t) = \int_{\mathbb{R}} f(x, t - s) \frac{1}{2^{2j}} \Delta\left(\frac{s}{2^{2j}}\right) ds.$$

► But this is a bit tricky to use, in the presence of the Radon transform:

- ▶ e.g. when $0 = j < k$, let's try to gain some cancellation between j and k from $\mathcal{I}_k^P \Delta_j f$. Note

$$\mathcal{I}_k^P \Delta_0 f(x, t) = \int_{\mathbb{R}^3} f(x-y, t-s) \frac{1}{2^{2k}} \eta\left(\frac{y}{2^k}\right) e^{iP\left(\frac{y}{2^k}\right)} \Delta(s-|y|^2) dy ds.$$

- ▶ Even if say $\int_{\mathbb{R}} \Delta(s) ds = 0$, or $\Delta(s) = \tilde{\Delta}'(s)$ for some function $\tilde{\Delta}$, it is not immediate how one can gain 2^{-k} by integrating by parts.
- ▶ This difficulty only arises from the presence of Radon behaviour in \mathcal{I}_k^P !
- ▶ Fortunately, one can succeed by using yet another TT^* argument here.
